ABSTRACT
This paper presents modified neural network for dynamic control and operation of a hybrid generation systems. PV and wind power are the primary power sources of the system to take full advantages of renewable energy, and the diesel-engine is used as a backup system. The simulation model of the hybrid system was developed using MATLAB Simulink. To achieve a fast and stable response for the real power control, the intelligent controller consists of a Radial Basis Function Network (RBFN) and an modified Elman Neural Network (ENN) for maximum power point tracking (MPPT). The pitch angle of wind turbine is controlled by ENN, and the PV system uses RBFN, where the output signal is used to control the DC / DC boost converters to achieve the MPPT. And the results show the hybrid generation system can effectively extract the maximum power from the PV and wind energy sources.

Keywords: Photovoltaic system, radial basis function network, Elman neural network, maximum power point tracking, diesel-engine.

1. Introduction

Wind and solar power generation are two of the most promising renewable power generation technologies. Variable-speed wind turbines have many advantages that are well documented in the literature [1], [2]. The wind turbine can operate with maximum aerodynamic efficiency, and the power fluctuations can be absorbed as an inertial energy in the blades. In some applications, the wind turbine may be augmented by an additional power source, usually a diesel generator. These systems are called wind–diesel systems [3], [4] and may be used to supply electricity energy to stand-alone loads, e.g., small villages that are not connected to the main utility. Most diesel generation systems operate at a constant speed due to the restriction of constant frequency at the generator terminals. However, diesel engines have high fuel consumption when operating with light load and constant speed. In order to improve the efficiency and avoid wetstacking, a minimum load of about 30% to 40% is usually recommended by the manufacturers [5]. Variable-speed operation can increase the efficiency, where the fuel consumption can be reduced up to 40% [5], especially when operating with a light load. Moreover, the life expectancy can increase with a lower thermal signature. To avoid the frequent start/stop of the diesel generator, an energy storage system is often used.

Topologies of the power electronic converter for Maximum Power Point Tracking (MPPT) [6] and voltage conversion are studied in this paper. The maximum power point of photovoltaic array is variational, so a search algorithm is needed according to the current-voltage (I-V) and power-voltage (P-V) characteristics of the solar cell. The Perturbation and Observation (P&O) MPPT algorithm is commonly used, due to its ease of implementation. It is based on the observation that if the operating voltage of the PV array is perturbed in a given direction and the power drawn from the photovoltaic (PV) array increases, which means that the operating point is moving toward the MPP, so the operating voltage must be further perturbed in the same direction. Otherwise, with the operating point moving away from the MPP, the direction of the operating voltage perturbation must be reversed. By using P&O method, impedance matching is conducted between boost converter and photovoltaic array in order to realize the MPPT function [7], [8].

The general requirements of MPPT are: simple, low cost, quick tracking when condition changes.
and small output power fluctuation. The traditional methods are simple and low cost without good tracking performance, such as hill climbing, P&O, and incremental conductance, etc. Novel methods are developed with higher accuracy but complex process, such as optimum gradient method, fuzzy logic control (FLC) and neural networks (NN). These technique could also be costly, difficult to implement, and may not be stable enough [7], [8]. RBFN has a faster convergence property than common multiplayer-perceptron (MLP) neural networks, but with a simpler network structure. RBFN also has a similar feature as the fuzzy-logic system, where the output value is calculated using the weighted-sum method, and the number of nodes in the hidden layer is the same as that of the “if-then” rules of the fuzzy system. The receptive field functions of the RBFN are also similar to the membership functions of the premise part of the fuzzy-logic system. With advantages of multiple facets and the self-adapting capabilities, RBFN is very useful for controlling nonlinear and time-varying dynamic systems where uncertainties and parameter variations need extra attention [9].

2. Analysis of system overview

The proposed PV and diesel-wind hybrid system is shown in Figure 1. Dynamic models of the main components were developed using MATLAB/Simulink, consisting of

(1) wind energy conversion system (WECS),
(2) diesel generator system,
(3) PV generation system.

![Figure 1. The proposed hybrid system.](image)

2.1 Wind Energy Conversion System

In order to capture the maximal wind energy, it is necessary to install the power electronic devices between the WTG and the grid where the frequency is constant. The input of a wind turbine is the wind and the output is the mechanical power turning the generator rotor [6]. For a variable speed wind turbine, the output mechanical power available from a wind turbine could be expressed as

\[ P_m = \frac{1}{2} \rho A C_p (\lambda, \beta) V_w^3 \]  

(1)

where \( \rho \) and \( A \) are air density and the area swept by blades, respectively. \( V_w \) is the wind velocity (m/sec), and \( C_p \) is called the power coefficient, and is given as a nonlinear function of the tip speed ratio (TSR) \( \lambda \) with

\[ \lambda = \frac{\omega_r r}{V_w} \]  

(2)

where \( r \) is wind turbine blade radius, and \( \omega_r \) is the turbine speed. \( C_p \) is a function of \( \lambda \) and the blade pitch angle \( \beta \).

2.2 Diesel-Generator Set Model and Excitation System

The Diesel generator set (DGS) model is made of combustion, drive train, and synchronous generator models. A common governor model is used in this paper; the essential features can be described by the transfer function described in [3]. The excitation system used in diesel generator is Type-1 excitation model taken from IEEE standard 421.5 [10].

2.3 Photovoltaic Array Model

PV cell is a p-n junction, with characteristics similar to diodes. Parameters of the PV cell are shown in Figure 2. The relation between the array terminal current and voltage is [7].

\[ V_{pv} = \frac{nKT}{q} \ln \left( \frac{I_{sc}}{I_{pv}} + 1 \right) \]  

(3)
where $R_s$ and $R_{sh}$ are series and shunt resistances, respectively. $I_{SC}$ is the light induced current, $n$ is the ideality factor of p-n junction, $I_{PVO}$ is the diode saturation current, $K$ is Boltzmann constant $(8.63 \times 10^{-5} \text{ J/°K})$, and $q$ is the electronic charge. $I_{SC}$ depends on the irradiance level $S$ and the array temperature $T$ with

$$I_{SC} = I_{ref} \left[1 + h(t(T_c - T_{ref}))\right] \frac{S}{S_{ref}}$$

(5)

where $I_{ref}$ is the short-circuit current under the reference irradiance strength $S_{ref}$ and temperature $T_{ref}$, $ht$ is cell module temperature coefficient, while $I_{PVO}$ depend on $T$ only [7], [11].

3. MPPT Control Algorithm of PV System

With the cost of PV cell, it is necessary to implement MPPT to have the voltage operating close to the maximum power point under the changing environment. The proposed PV system is composed of an array of 4x4 panels, a dc/dc converter, a battery storage, dc/ac inverter and a control algorithm, generally performed by a microcontroller to track the maximum power continuously. MPPT is also used to provide a constant voltage to the required load.

3.1 Perturbation and Observation Method

The most common method in this field is the P&O method [12]. It periodically increases or decreases the PV cell’s voltage as mentioned before to seek the maximum power point. In this paper, a variable step method is proposed to search for the maximum power point, where the step lengths are adjusted according to the distances to the MPP. The ratio of the variation of power ($P$) to voltage ($V$) is considered as the step length of duty ratio $D$, which is actually the slope of each operating point under very short sampling time. Figure 3 shows the control block of the P&O method.

3.2 RBFN Controller Design

Once the IENN is initialized, a supervised learning is used to train a three-layer RBFN neural network with a boost converter shown in Figure 4 is adopted to implement the controller [13], [14] where the control law $V_{MPPT}$ is generated, and $x_1 = V_{PV}$, $x_2 = I_{PV}$ and $x_3 = Temperature$. In the proposed RBFN, the number of units in the input, hidden, and output layers are three, nine and one, respectively. In order to apply RBFN control, PV system in Figure 5 is linearized in this section. The PWM module is used to generate PWM pulses to control the duty cycle of the switch.

Layer 1. Input Layer

The nodes in this layer are used to directly transmit the numerical inputs to the next layer. The net input and output are represented as

$$net_i^{(1)} = x_i^{(1)}(N)$$

(6)

$$y_i^{(1)}(N) = f_i^{(1)}(net_i^{(1)}(N)) = net_i^{(1)}(N), \quad i = 1,2$$

(7)
Layer 2. Hidden Layer

Every node performs a Gaussian function. The Gaussian function, a particular example of radial basic functions, is used here as a membership function. Then

\[ j^{(2)}_j(N) = f^{(2)}_j (net^{(2)}_j(N)) = \exp(\sum_{j} (X - M_j)^T \Sigma_j^{-1} (X - M_j)) \]  

(8)

where \( M_j = [m_{1j}, m_{2j}, ..., m_{ij}]^T \) and \( \Sigma_j = \text{diag}[1/\sigma_{1j}^2, 1/\sigma_{2j}^2, ..., 1/\sigma_{ij}^2]^T \) denote the mean and the standard deviation (STD) of the Gaussian function.

Layer 3. Output Layer

The single node \( k \) in this layer is denoted by \( \Sigma \), which computes the overall output as the summation of all incoming signals by

\[ net^{(3)}_k = \sum_j w_j y^{(2)}_j (N) \]  

(10)

where \( w_j \) are the connective weight between the hidden and the output layers.

\[ y^{(3)}_k (N) = f^{(3)}_k (net^{(3)}_k (N)) = net^{(3)}_k (N) \]  

(11)

Figure 4. Configuration of the RBFN control system.

Figure 5. Structure of the three-layer RBFN.
Once the RBFN has been initialized, a supervised learning law of gradient descent is used to train this system. The derivation is the same as that of the back-propagation algorithm. It is employed to adjust the parameters \( m_i \), \( \sigma_j \), and \( w_{ij} \) of the RBFN by using the training patterns. By recursive application of the chain rule, the error term for each layer is calculated, and updated. The adjustment of the parameters for learning and the weight of links enhances the performance of PV systems. The purpose of supervised learning is to minimize the error function \( E \) expressed as

\[
E = \frac{1}{2}(V_{dc} - V_{\text{MPPT}})^2
\]

where \( V_{dc} \) and \( V_{\text{MPPT}} \) represent the reference output voltage and the actual output voltage. A common supervised training algorithm is used in this paper, the essential features can be described in [13], [14].

4. MPPT Control Algorithm of Wind Energy System

4.1 Wind Energy Controller Design

The wind power generation system studied in this paper is shown in Figure 6, composed of an induction generator, a current control PWM ac/dc converter, a field-orientation mechanism, including the coordinate translator, a current controlled dc/ac inverter and the MPPT controller where PI and ENN were studied in this paper. A power controller of the dc/ac inverter in Figure 6 may be constructed in normal operation of the hybrid system. The dc-bus voltage is regulated at a constant value so that real power generation from the wind turbine can pass into the grid. By using the reference frame theory and the linearization technique, the field-oriented induction generator system can be reasonably represented by the control system block diagram shown in Figure 7.

4.2 Modified Elman Neural Network (ENN) Controller Design

The architecture of the proposed ENN including the input layer, the hidden layer, the context layer and output layer with two inputs and one output is shown in Figure 7, where the control law is defined as \( i_q^* \), and the ENN input is \( e_1^{(1)} \) and \( e_2^{(1)} \) with \( e_1^{(1)} = P_{\text{ref}} - P_{\text{out}} \) and \( e_2^{(1)} = \beta_c - \beta \) in this study. The proposed ENN [15-16], takes the feedback into account, and a better learning efficiency can be obtained.

Moreover, to make the neurons sensitive to the history of input data, self-connections of the context nodes and output feedback node are added. So, the proposed ENN combines the ability of dealing with nonlinear problems and can effectively improve the convergence precision and reduce learning time. The signal propagation and the basic function in each layer is introduced below.

Layer 1. Input Layer

In the input layer, the node is defined by

\[
net_i^{(1)} = e_i^{(1)}(k)
\]

\[
x_i^{(1)}(k) = f_i^{(1)}(net_i^{(1)}(k)) = net_i^{(1)}
\]

where \( k \) represents the \( k_{\text{th}} \) iteration, \( e_i^{(1)}(k) \) and \( x_i^{(1)}(k) \) are the input and the output of the layer.

Layer 2. Hidden Layer

In the hidden layer, the node is defined by

\[
net_j^{(2)} = \sum_i W_{ij} \times x_i^{(1)}(k) + \sum_r W_{jr} \times x_r^{(3)}(k)
\]

\[
x_j^{(2)}(k) = \frac{1}{1 + \exp(-net_j^{(2)})}
\]
where $x_i^{(1)}$, $x_r^{(3)}$ and $x_j^{(2)}(k)$ are input and $x_j^{(2)}(k)$ is output of the hidden layer, $x_r^{(3)}(k)$ is also the output of the context layer, and $W_j$ and $W_j$ are the connecting weights of input neurons to hidden neurons and context neurons to hidden neurons, respectively.

**Layer 3. Context Layer**

In the context layer, the node input and output are represented as

$$x_r^{(3)}(k) = \alpha x_r^{(3)}(k-1) + x_j^{(2)}(k-1)$$  \hspace{1cm} (17)

where $0 \leq \alpha < 1$ is the self-connecting feedback gain.

**Layer 4. Output Layer**

In the output layer, the node input and output are represented as

$$net_o^{(4)}(k) = \sum_j W_j x_j^{(2)}(k)$$  \hspace{1cm} (18)

$$y_o^{(4)}(k) = f_o^{(4)}(net_o^{(4)}(k)) = net_o^{(4)}(k) = i_q^*$$  \hspace{1cm} (19)

where $W_j$ is the connecting weight of hidden neurons to output neurons, and $y_o^{(4)}(k)$ is the output of the modified ENN and also the control effort of the proposed controller.

![Figure 7. Architecture of the ENN.](image-url)
Once the ENN has been initialized, a supervised learning is used to train this system based on gradient descent. The derivation is the same as that of the back-propagation algorithm. It is employed to adjust the parameters $W_{jo}$, $W_{ri}$, and $W_{ij}$ of the ENN by using the training patterns. By recursive application of the chain rule, the error term for each layer is calculated, and updated. The purpose of supervised learning is to minimize the error function $E$ expressed as

$$E = \frac{1}{2} (P_{\text{out}} - P_{\text{ref}})^2 = \frac{1}{2} e^2$$  \hspace{1cm} (20)

where $P_{\text{out}}$ and $P_{\text{ref}}$ represent the actual output power and the reference output power of the generator, respectively, and $e$ denotes the tracking. A common supervised training algorithm is used in this paper, the essential features can be described in [15]-[17].

5. Simulation Results

The hybrid system shown in Figure 1 is implemented in the Matlab / Simpower environment. Many tests were conducted to show performance of the model under various conditions, with the comparison of various MPPT schemes including the typical PI control and P&O method.

5.1 MPPT System Performance

Wind power MPPT

Time domain simulation was run for the hybrid power system with constant load under sufficient wind and irradiance. The output power from WECS is shown in Figure 8. From Figure 8, it can be seen that the ENN controller provides a better control performance than PI with less transient and smaller vibrations. The transient response of the design at the start point can be seen clearly that PI fluctuate much more, but ENN oscillates only slightly. The average power is 1.88KW. Compared with that of the PI control, it increases by 6.2%. With different wind speeds, the performance comparison is shown in Table 1.

Table 1. Performance comparison of ENN and PI Controller.
PV Power MPPT

The output power from PV is shown in Figure 9. From Figure 9, we can see that the RBFN controller provides a better performance than P&O, both in the transient and the stability. The average power is 2.7KW. Compared with that of P&O, it increases by 14.89%. The RBFN method can quickly and accurately track the maximum power output for PV array.

5.2 MPPT with Load Change

With sufficient wind and irradiance, Figure 10 and 11 show the comparison of the proposed algorithms with PI and P&O methods for a sudden load change from 3KW to 4KW. The DC link voltage slightly decreases and then recovers in around 0.1 sec. The grid frequency response won’t change as can be seen in Figure 12. The proposed method can track faster with a more stable output power under load disturbance.

Figure 9. Power response of the PV system.

Figure 10. Wind power generation in load varied condition.
6. Conclusion

In this paper, a PV and diesel-wind hybrid generation system was proposed and implemented. This stand-alone hybrid generation system can effectively extract the maximum power from the wind and PV energy sources. From the case studies, it shows that voltage and power can be well controlled in the hybrid system under a changing environment. An efficient power sharing technique among energy sources are successfully demonstrated with more efficiency, a better transient and more stability, even under disturbance.
The simulation model of the hybrid system was developed using MATLAB/Simulink. The load frequency is regulated by the diesel generator by imposing the rotor currents with the slip frequency. The electrical torque of the WECS generator is controlled to drive the system to the rotational speed where maximum energy can be captured. Depending on the load size and the power supplied by the WECS generator, the control system regulates the DGS rotational speed to minimize the fuel consumption.
